## Introduction

A sound wave is a longitudinal wave, which alternately pushes and pulls the material through which it propagates. The amplitude disturbance is thus parallel to the direction of propagation.

Sound waves can propagate through the air, water, Earth, wood, metal rods, stretched strings, and any other physical substance.

The purpose of this tutorial is to give formulas for calculating the speed of sound. Separate formulas are derived for a gas, liquid, and solid.

## General Formula for Fluids and Gases

The speed of sound c is given by

$$
\begin{equation*}
c=\sqrt{\frac{B}{\rho_{o}}} \tag{1}
\end{equation*}
$$

where

$$
B \text { is the adiabatic bulk modulus, }
$$ $\rho_{o}$ is the equilibrium mass density.

Equation (1) is taken from equation (5.13) in Reference 1. The characteristics of the substance determine the appropriate formula for the bulk modulus.

## Gas or Fluid

The bulk modulus is essentially a measure of stress divided by strain. The adiabatic bulk modulus B is defined in terms of hydrostatic pressure P and volume V as

$$
\begin{equation*}
B=\frac{\Delta P}{-\Delta V / V} \tag{2}
\end{equation*}
$$

Equation (2) is taken from Table 2.1 in Reference 2.

An adiabatic process is one in which no energy transfer as heat occurs across the boundaries of the system.

An alternate adiabatic bulk modulus equation is given in equation (5.5) in Reference 1.

$$
\begin{equation*}
B=\rho_{o}\left(\frac{\partial P}{\partial \rho}\right)_{\rho_{0}} \tag{3}
\end{equation*}
$$

Note that

$$
\begin{equation*}
\left(\frac{\partial \mathrm{P}}{\partial \rho}\right)=\gamma \frac{\mathrm{P}}{\rho} \tag{4}
\end{equation*}
$$

where
$\gamma$ is the ratio of specific heats.
The ratio of specific heats is explained in Appendix A.
The speed of sound can thus be represented as

$$
\begin{equation*}
c=\sqrt{\gamma \frac{\mathrm{P}_{\mathrm{o}}}{\rho_{\mathrm{o}}}} \tag{5}
\end{equation*}
$$

Equation (5) is the same as equation (5.18) in Reference 1.

## Perfect Gas

An alternate formula for the speed of sound in a perfect gas is

$$
\begin{equation*}
\mathrm{c}=\sqrt{\gamma\left(\frac{\mathrm{R}}{\mathrm{M}}\right) \mathrm{T}_{\mathrm{k}}} \tag{6a}
\end{equation*}
$$

where
$\gamma$ is the ratio of specific heats,
M is the molecular mass,
R is the universal gas constant,
$\mathrm{T}_{\mathrm{k}}$ is the absolute temperature in Kelvin.
Molecular mass is explained in Appendix A. The speed of sound in the atmosphere is given in Appendix B.

Equation (6a) is taken from equations (5.19) and (A9.10) in Reference 1.
The speed of sound in a gas is directly proportional to absolute temperature.

$$
\begin{equation*}
\frac{\mathrm{c}_{1}}{\mathrm{c}_{2}}=\sqrt{\frac{\mathrm{T}_{\mathrm{k}, 1}}{\mathrm{~T}_{\mathrm{k}, 2}}} \tag{6b}
\end{equation*}
$$

$\underline{\text { Liquid }}$
A special formula for the speed of sound in a liquid is

$$
\begin{equation*}
\mathrm{c}=\sqrt{\frac{\gamma \mathrm{B}_{\mathrm{T}}}{\rho_{\mathrm{o}}}} \tag{7}
\end{equation*}
$$

where
$\gamma \quad$ is the ratio of specific heats,
$\mathrm{B}_{\mathrm{T}}$ is the isothermal bulk modulus,
$\rho_{o}$ is the equilibrium mass density.
Equation (7) is taken from equation (5.21) in Reference 1.
The isothermal bulk modulus is related to the adiabatic bulk modulus.

$$
\begin{equation*}
\mathrm{B}=\gamma \mathrm{B}_{\mathrm{T}} \tag{8}
\end{equation*}
$$

Solid
The speed of sound in a solid material with a large cross-section is given by

$$
\begin{equation*}
c=\sqrt{\frac{B+\left(\frac{4}{3}\right) G}{\rho}} \tag{9}
\end{equation*}
$$

where
G is the shear modulus, $\rho$ is the mass per unit volume.

Equation (9) is taken from equation (6.41) in Reference 1. The c term is referred to as the bulk or plate speed of longitudinal waves.

The shear modulus can be expressed as

$$
\begin{equation*}
G=\frac{E}{2(1+v)} \tag{10}
\end{equation*}
$$

where
E is the modulus of elasticity, $v$ is Poisson's ratio.

Equation (10) is taken from Table 2.2 in Reference 2.
Substitute equation (10) into (9).

$$
\begin{gather*}
c=\sqrt{\frac{B+\left(\frac{4}{3}\right)\left(\frac{E}{2(1+v)}\right)}{\rho}}  \tag{11a}\\
c=\sqrt{\frac{B+\left(\frac{2}{3}\right)\left(\frac{E}{1+v}\right)}{\rho}} \tag{11b}
\end{gather*}
$$

The bulk modulus for an isotropic solid is

$$
\begin{equation*}
B=\frac{E}{3(1-2 v)} \tag{12}
\end{equation*}
$$

where
E is the modulus of elasticity, $v$ is Poisson's ratio.

The modulus of elasticity is also called Young's modulus.
Equation (12) is taken from the Definition Chapter in Reference 3. It is also given in Table 2.2 of Reference 2.

Substitute equation (12) into equation (11b).

$$
\begin{equation*}
c=\sqrt{\frac{\left(\frac{E}{3(1-2 v)}\right)+\left(\frac{2}{3}\right)\left(\frac{E}{1+v}\right)}{\rho}} \tag{13}
\end{equation*}
$$

The next steps simplify the algebra.

$$
\begin{equation*}
c=\sqrt{\left(\frac{E}{\rho}\right)\left(\left(\frac{1}{3(1-2 v)}\right)+\left(\frac{2}{3}\right)\left(\frac{1}{1+v}\right)\right)} \tag{14}
\end{equation*}
$$

$$
\begin{gather*}
c=\sqrt{\left(\frac{E}{\rho}\right)\left(\frac{(1+v)+2(1-2 v)}{3(1-2 v)(1+v)}\right)}  \tag{15}\\
c=\sqrt{\left(\frac{E}{\rho}\right)\left(\frac{3-3 v}{3(1-2 v)(1+v)}\right)}  \tag{16}\\
c=\sqrt{\left(\frac{E}{\rho}\right)\left(\frac{1-v}{(1-2 v)(1+v)}\right)} \tag{17}
\end{gather*}
$$

Equation (17) is also given in Chapter 2 of Reference 4.
The Poisson terms in equation (17) account for a lateral effect, which can be neglected if the cross-section dimension is small, compared to the wavelength. In this case, equation (17) simplifies to

$$
\begin{equation*}
c=\sqrt{\frac{E}{\rho}} \tag{18}
\end{equation*}
$$

String
Consider a string with uniform mass per length $\rho_{\mathrm{L}}$. The string is stretched with a tension force $T$. The phase speed c is given by

$$
\begin{equation*}
c=\sqrt{\frac{T}{\rho_{\mathrm{L}}}} \tag{19}
\end{equation*}
$$

This speed is the phase speed of transverse traveling waves.
Equation (19) is taken from equation (2.6) in Reference 1.

## Membrane

Consider a membrane with uniform mass per area $\rho_{\mathrm{a}}$. The membrane is assumed to be thin, with negligible stiffness.

The membrane is stretched with a tension force per length $\mathrm{T}_{\mathrm{L}}$. The tension is assumed to be uniform throughout the membrane.

The transverse phase speed c is given by

$$
\begin{equation*}
\mathrm{c}=\sqrt{\frac{\mathrm{T}_{\mathrm{L}}}{\rho_{\mathrm{a}}}} \tag{20}
\end{equation*}
$$

This speed is the phase speed of transverse traveling waves.
Equation (20) is the same as equation (4.3) in Reference 1.

## Special Topics

Appendix B gives the variation of the speed of sound in the atmosphere with altitude.
Appendix C gives the speed of sound in seawater.

## Properties

Pertinent properties of solids, liquids, and gases are given in Tables 1a, 1b, 2, and 3, respectively.

| Table 1a. Solids |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Solid | $\begin{aligned} & \text { Density } \\ & \left(\mathrm{kg} / \mathrm{m}^{3}\right) \end{aligned}$ | Elastic Modulus (Pa) | Shear Modulus (Pa) | Poisson's Ratio | Speed of Sound ( $\mathrm{m} / \mathrm{sec}$ ) |  |

Note: $1(\mathrm{~kg} / \mathrm{kgmole})=1(\mathrm{lbm} / \mathrm{lbmole})$

## Examples

Air
Calculate the speed of sound in air for a temperature of 70 degrees F (294.26 K).
The properties for air are

$$
\begin{aligned}
& \gamma=1.402 \\
& \mathrm{M}=28.97 \mathrm{~kg} / \mathrm{kgmole}
\end{aligned}
$$

The universal gas constant is

$$
\mathrm{R}=8314.3 \mathrm{~J} /(\mathrm{kgmole} \cdot \mathrm{~K})
$$

The specific heat ratio is taken from Appendix 10 of Reference 1. The molecular mass and gas constant values are taken from Reference 5.

The formula for the speed of sound is

$$
\begin{aligned}
& \mathrm{c}=\sqrt{\gamma\left(\frac{\mathrm{R}}{\mathrm{M}}\right) \mathrm{T}_{\mathrm{k}}} \\
& \mathrm{c}=\sqrt{1.402\left(\frac{\mathrm{kgmole}}{28.97 \mathrm{~kg}}\right)\left(8314.3 \frac{\mathrm{~J}}{\mathrm{kgmole} \cdot \mathrm{~K}}\right)(294.26 \mathrm{~K})} \\
& \mathrm{c}=344 \mathrm{~m} / \mathrm{sec} \\
& \mathrm{c}=1130 \mathrm{ft} / \mathrm{sec}
\end{aligned}
$$

## Solid, Aluminum Rod

Calculate the speed of sound in an aluminum rod. Assume that the diameter is much smaller than the wavelength.

The material properties for aluminum are:

$$
\begin{aligned}
& \mathrm{E}=70\left(10^{9}\right) \mathrm{Pa} \\
& \rho=2700 \mathrm{~kg} / \mathrm{m}^{3}
\end{aligned}
$$

These properties are taken from Reference 6. The speed of sound is

$$
\begin{aligned}
& c=\sqrt{\frac{E}{\rho}} \\
& c=\sqrt{\frac{70\left(10^{9}\right) \mathrm{Pa}}{2700 \mathrm{~kg} / \mathrm{m}^{3}}} \\
& c=5100 \mathrm{~m} / \mathrm{sec} \\
& c=16,700 \mathrm{ft} / \mathrm{sec}
\end{aligned}
$$

## APPENDIX A

## Ratio of Specific Heats

The ratio of specific heats is defined as

$$
\begin{equation*}
\gamma=\frac{C p}{C v} \tag{A-1}
\end{equation*}
$$

where

Cp is the heat capacity at constant pressure,
Cv is the heat capacity at constant volume.

## Molecular Mass

Molecular mass is also called be the following names:

1. Molecular weight
2. Molal mass

Molecular mass is the mass per mole of a material.
One mole is defined as $6.023\left(10^{23}\right)$ particles. This is called Avogadro's number. It is also the number of atoms in a "gram atom."

For carbon 12, the molecular mass is $12 \mathrm{~kg} / \mathrm{kgmole}=12 \mathrm{~g} / \mathrm{gmole}=12 \mathrm{lbm} / \mathrm{lbmole}$. The mole is defined in such a way that one kgmole of a substance contains the same number of molecules as 12 kg of carbon 12. Likewise, one lbmole contains the same number of molecules as 12 lbm of carbon 12.

## APPENDIX B

## Variation of the Speed of Sound in the Atmosphere with Altitude

The pressure, temperature, density and speed of sound for the international standard atmosphere (ISA) can be calculated for a range of altitudes from sea level upward. These parameters are obtained from the hydrostatic equation for a column of air. The air is assumed to be a perfect gas.

The atmosphere consists of two regions.
The troposphere is the region between sea level and an altitude of approximately 11 km ( 36,089 feet). In reality, the boundary may be at 10 to 15 km depending on latitude and time of year. The temperature lapse rate in the troposphere is taken as $\mathrm{L}=6.5 \mathrm{Kelvin} / \mathrm{km}$. The actual value depends on the season, weather conditions, and other variables.

The stratosphere is the region above 11 km and below 50 km . The stratosphere is divided into two parts for the purpose of this tutorial.

The lower stratosphere extends from 11 km to 20 km . The temperature remains constant at 217 Kelvin $(-69.1 \mathrm{~F})$ in the lower stratosphere.

The upper stratosphere extends from 20 km to 50 km . The temperature rises in the upper stratosphere.

## Basic Equations

The hydrostatic equation for pressure P and altitude h is

$$
\begin{equation*}
\frac{\mathrm{dP}}{\mathrm{dh}}=-\rho \mathrm{g} \tag{B-1}
\end{equation*}
$$

where

$$
\begin{aligned}
& \rho=\text { mass density }, \\
& g=\text { gravitational acceleration } .
\end{aligned}
$$

The perfect gas equation is

$$
\begin{equation*}
\mathrm{P}=\rho \frac{\mathrm{R}}{\mathrm{M}} \mathrm{~T}_{\mathrm{k}} \tag{B-2}
\end{equation*}
$$

where

## R is the universal gas constant,

M is the molecular weight,
$\mathrm{T}_{\mathrm{k}}$ is the absolute temperature in Kelvin.

Note that for air,

$$
\begin{align*}
& \frac{\mathrm{R}}{\mathrm{M}}=\frac{8314.3 \mathrm{~J} /(\mathrm{kgmole} \cdot \mathrm{~K})}{28.97 \mathrm{~kg} / \mathrm{kgmole}}  \tag{B-3}\\
& \frac{\mathrm{R}}{\mathrm{M}}=287 \frac{\mathrm{~J}}{\mathrm{~kg} \cdot \mathrm{~K}}  \tag{B-4}\\
& \frac{\mathrm{R}}{\mathrm{M}}=287 \frac{\mathrm{~m}^{2} / \mathrm{sec}^{2}}{\mathrm{~K}} \tag{B-5}
\end{align*}
$$

## Troposphere

The temperature lapse equation for the troposphere is

$$
\begin{equation*}
\mathrm{T}=\mathrm{T}_{\mathrm{o}}-\mathrm{Lh} \tag{B-6}
\end{equation*}
$$

Recall the formula for the speed of sound in a perfect gas.

$$
\begin{equation*}
\mathrm{c}=\sqrt{\gamma\left(\frac{\mathrm{R}}{\mathrm{M}}\right) \mathrm{T}_{\mathrm{k}}} \tag{B-7}
\end{equation*}
$$

The speed of sound in the troposphere is thus

$$
\begin{equation*}
\mathrm{c}=\sqrt{\gamma\left(\frac{\mathrm{R}}{\mathrm{M}}\right)\left(\mathrm{T}_{\mathrm{o}}-\mathrm{Lh}\right)} \tag{B-8}
\end{equation*}
$$

The standard sea level temperature is $\mathrm{T}_{\mathrm{o}}=288$ Kelvin. Again, $\mathrm{L}=6.5 \mathrm{Kelvin} / \mathrm{km}$ for the troposphere.

Substitute equation (B-6) into (B-2) to obtain the perfect gas law for the troposphere.

$$
\begin{equation*}
\mathrm{P}=\rho \frac{\mathrm{R}}{\mathrm{M}}\left[\mathrm{~T}_{\mathrm{o}}-\mathrm{Lh}\right] \tag{B-9}
\end{equation*}
$$

The density in the troposphere can thus be expressed as

$$
\begin{equation*}
\rho=\frac{\mathrm{P}}{\frac{\mathrm{R}}{\mathrm{M}}\left[\mathrm{~T}_{\mathrm{o}}-\mathrm{Lh}\right]} \tag{B-10}
\end{equation*}
$$

Solve the hydrostatic equation for a constant lapse rate. The resulting equation gives the pressure variation with altitude. Neglect the variation of gravity with altitude. Rewrite equation (B-1).

$$
\begin{equation*}
d P=-\rho g d h \tag{B-11}
\end{equation*}
$$

Substitute equation (B-10) into (B-11).

$$
\begin{align*}
& \mathrm{dP}=-\frac{\mathrm{P}}{\frac{\mathrm{R}}{\mathrm{M}}\left[\mathrm{~T}_{\mathrm{o}}-\mathrm{Lh}\right]} \mathrm{gdh}  \tag{B-12}\\
& \frac{\mathrm{dP}}{\mathrm{P}}=-\frac{\mathrm{g}}{\frac{\mathrm{R}}{\mathrm{M}}\left[\mathrm{~T}_{\mathrm{o}}-\mathrm{Lh}\right]} \mathrm{dh} \tag{B-13}
\end{align*}
$$

The hat sign is added in order to prevent confusion between the integration variables and the limits.

$$
\begin{align*}
& \int_{\mathrm{P}_{\mathrm{O}}}^{\mathrm{P}} \frac{\mathrm{~d} \hat{\mathrm{P}}}{\hat{\mathrm{P}}}=-\int_{0}^{\mathrm{h}} \frac{\mathrm{~g}}{\frac{\mathrm{R}}{\mathrm{M}}\left[\mathrm{~T}_{\mathrm{o}}-\mathrm{Lh}\right]} \mathrm{d} \mathrm{\hat{h}}  \tag{B-14}\\
& \left.\ln [\hat{\mathrm{P}}]\right|_{\mathrm{P}_{\mathrm{O}}} ^{\mathrm{P}}=\left.\frac{\mathrm{Mg}}{\mathrm{LR}} \ln \left[\mathrm{~T}_{\mathrm{o}}-\mathrm{Lh}\right]\right|_{0} ^{\mathrm{h}}  \tag{B-15}\\
& \ln \left[\frac{\mathrm{P}}{\mathrm{P}_{\mathrm{O}}}\right]=\frac{\mathrm{Mg}}{\mathrm{LR}}\left\{\ln \left[\mathrm{~T}_{\mathrm{o}}-\mathrm{Lh}\right]-\ln \left[\mathrm{T}_{\mathrm{O}}\right]\right\}  \tag{B-16}\\
& \ln \left[\frac{\mathrm{P}}{\mathrm{P}_{\mathrm{O}}}\right]=\frac{\mathrm{Mg}}{\mathrm{LR}}\left\{\ln \left[\frac{\mathrm{~T}_{\mathrm{O}}-\mathrm{Lh}}{\mathrm{~T}_{\mathrm{O}}}\right]\right\} \tag{B-17}
\end{align*}
$$

$$
\begin{equation*}
\left[\frac{\mathrm{P}}{\mathrm{P}_{\mathrm{O}}}\right]=\left[\frac{\mathrm{T}_{\mathrm{o}}-\mathrm{Lh}}{\mathrm{~T}_{\mathrm{O}}}\right]^{\left[\frac{\mathrm{Mg}}{\mathrm{LR}}\right]} \tag{B-18}
\end{equation*}
$$

The pressure in the troposphere is thus

$$
\begin{equation*}
\mathrm{P}=\mathrm{P}_{\mathrm{O}}\left[\frac{\mathrm{~T}_{\mathrm{O}}-\mathrm{Lh}}{\mathrm{~T}_{\mathrm{O}}}\right]^{\left[\frac{\mathrm{Mg}}{\mathrm{LR}}\right]} \tag{B-19}
\end{equation*}
$$

Note that the sea level pressure is $\mathrm{P}_{\mathrm{O}}=101.3 \mathrm{kPa}$.
The density in the troposphere is obtained from equations (B-10) and (B-19).

$$
\begin{equation*}
\rho=\frac{\mathrm{P}_{\mathrm{O}}\left[\frac{\mathrm{~T}_{\mathrm{O}}-\mathrm{Lh}}{\mathrm{~T}_{\mathrm{O}}}\right]^{\left[\frac{\mathrm{Mg}}{\mathrm{LR}}\right]}}{\frac{\mathrm{R}}{\mathrm{M}}\left[\mathrm{~T}_{\mathrm{o}}-\mathrm{Lh}\right]} \tag{B-20}
\end{equation*}
$$

## Lower Stratosphere

Again, the temperature is constant in the lower stratosphere. The speed of sound is thus constant in the lower stratosphere.

$$
\begin{equation*}
\mathrm{dP}=-\rho \mathrm{gdh} \tag{B-21}
\end{equation*}
$$

Let $\mathrm{T}_{\mathrm{c}}$ be the constant temperature in the lower stratosphere.

$$
\begin{gather*}
d P=-\frac{P}{\frac{R T_{c}}{M}} g d h  \tag{B-22}\\
\frac{d P}{P}=-\frac{M g}{R T_{c}} d h \tag{B-23}
\end{gather*}
$$

The hat sign is added in order to prevent confusion between the integration variables and the limits.

$$
\begin{align*}
& \int_{\mathrm{P}_{1}}^{\mathrm{P}} \frac{\mathrm{~d} \hat{\mathrm{P}}}{\hat{\mathrm{P}}}=-\int_{\mathrm{h}_{1}}^{\mathrm{h}} \frac{\mathrm{Mg}}{\mathrm{RT}_{\mathrm{c}}} d \hat{\mathrm{~h}}  \tag{B-24}\\
& \left.\ln [\hat{\mathrm{P}}]\right|_{\mathrm{P}_{1}} ^{P}=\left.\frac{-\mathrm{Mg}_{g}}{\mathrm{RT}_{\mathrm{c}}} \hat{\mathrm{~h}}\right|_{\mathrm{h}_{1}} ^{\mathrm{h}}  \tag{B-25}\\
& \ln \left[\frac{\mathrm{P}}{\mathrm{P}_{1}}\right]=\frac{-\mathrm{Mg}}{\mathrm{RT}_{\mathrm{c}}}\left[\mathrm{~h}-\mathrm{h}_{1}\right]  \tag{B-26}\\
& \frac{\mathrm{P}}{\mathrm{P}_{1}}=\exp \left\{\frac{-\mathrm{Mg}^{R T_{c}}}{\mathrm{Re}_{\mathrm{c}}}\left[\mathrm{~h}-\mathrm{h}_{1}\right]\right\} \tag{B-27}
\end{align*}
$$

The pressure in the lower stratosphere is thus

$$
\begin{equation*}
\mathrm{P}=\mathrm{P}_{\mathrm{l}} \exp \left\{-\frac{\mathrm{Mg}}{\mathrm{RT}_{\mathrm{c}}}\left[\mathrm{~h}-\mathrm{h}_{1}\right]\right\} \tag{B-27}
\end{equation*}
$$

Note that $\mathrm{P}_{1}$ is the pressure at the lower altitude limit of the stratosphere.
The density in the lower stratosphere is thus

$$
\begin{equation*}
\rho=\frac{\mathrm{M}}{\mathrm{RT}_{\mathrm{k}}} \mathrm{P}_{1} \exp \left\{-\frac{\mathrm{Mg}}{\mathrm{RT}_{\mathrm{c}}}\left[\mathrm{~h}-\mathrm{h}_{1}\right]\right\} \tag{B-28}
\end{equation*}
$$

## Summary

The pressure, density, and speed of sound are given in Table B-1 for an altitude up to 20 km .

| Table B-1. Atmospheric Properties |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Altitude (km) | Pressure (kPa) | Mass Density $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$ | Temp. (Kelvin) | Temp. $\left({ }^{\circ} \mathrm{C}\right)$ | Speed of Sound (m/sec) |
| 0 | 101.3 | 1.226 | 288 | 14.9 | 340.2 |
| 1 | 89.85 | 1.112 | 282 | 8.4 | 336.3 |
| 2 | 79.47 | 1.007 | 275 | 1.9 | 332.4 |
| 3 | 70.09 | 0.9096 | 269 | -4.7 | 328.5 |
| 4 | 61.62 | 0.8195 | 262 | -11.2 | 324.5 |

| 14 | 14.11 | 0.2266 | 217 | -56.2 | 295 |
| 15 | 12.06 | 0.1936 | 217 | -56.2 | 295 |
| 16 | 10.30 | 0.1654 | 217 | -56.2 | 295 |
| 17 | 8.801 | 0.1413 | 217 | -56.2 | 295 |
| 18 | 7.519 | 0.1207 | 217 | -56.2 | 295 |
| 19 | 6.424 | 0.1032 | 217 | -56.2 | 295 |
| 20 | 5.489 | 0.0881 | 217 | -56.2 | 295 |

Again, the values in Table B-1 are approximate. The actual values depend on the time of day, season, weather conditions, etc.

## APPENDIX C

## The Speed of Sound in Seawater

The speed of sound in seawater at $13{ }^{\circ} \mathrm{C}$ is $1500 \mathrm{~m} / \mathrm{sec}$, per Table 2. This is a nominal value. The actual value depends on the depth, salinity, and temperature.

A number of empirical equations exist for determining the speed of sound in seawater. Reference 8 gives the following "Leroy" equation.

$$
\begin{align*}
\mathrm{c}= & 1492.9+3(\mathrm{~T}-10)-6\left(10^{-3}\right)(\mathrm{T}-10)^{2} \\
& -4\left(10^{-2}\right)(\mathrm{T}-18)^{2}+1.2(\mathrm{~S}-35) \\
& -\left(10^{-2}\right)(\mathrm{T}-18)(\mathrm{S}-35)+\mathrm{Z} / 61 \tag{C-1}
\end{align*}
$$

where
c is the speed of sound in $\mathrm{m} / \mathrm{sec}$
T is the temperature in ${ }^{\circ} \mathrm{C}$
S is the salinity in parts per thousand
Z is the depth in meters.

Equation (1) is accurate to $0.1 \mathrm{~m} / \mathrm{sec}$ for T less than $20^{\circ} \mathrm{C}$ and Z less than 8000 m .

An alternate equation is the Lovett equation given in Chapter 15 of Reference 6.
